1. Introduction

1.1 Background

ITPEnergised were commissioned by Renewable Energy Systems UK and Ireland Ltd (RES) (the applicant) to undertake a Peat Landslide Hazard and Risk Assessment (PLHRA) at the proposed Longcroft Wind Farm (the ‘proposed development’), located in the south-west of the Lammermuir Hills, approximately 8.5km north of Lauder, Scottish Borders, at E354410, N655930, shown in Figure 1.

The site primarily comprises heather moorland or rough grassland, with a series of summits forming a plateau rising steeply from Whalplaw Burn and Soonhope Burn. A single lane track leads south-west of the site boundary to join the A697. The proposed development comprises 19 wind turbines and associated infrastructure, as shown in Figure 2.

This PLHRA was led by David Nisbet, Head of Geology, Peat & Hydrology at ITPEnergised. David has a BSc in Earth Science and 11 years’ experience in geology and environmental consultancy. David has led geology and peat assessments on many renewable energy and electrical transmission projects across the United Kingdom and Ireland, including PLHRA, Peat Management, Engineering Geological Assessment and Carbon Balance calculations.

The assessment has been undertaken in line with best practice guidance^{1, 2} issued by the Scottish Government for investigation, assessment, and reporting for wind farms in peat areas. Where relevant, reference is also made to guidance published by, the Scottish Environmental Protection Agency (SEPA) and wind farm constriction good practice guidance³.

Although peat slides are naturally occurring, in the wake of high profile peat slides arising during construction of Derrybrien Wind Farm in 2003 (and more recently at Meenbog in 2020) further consideration of the impact on peat instability of siting developments on peatlands is required.

Blanket bog is the most common peat habitat in the UK and is associated with thick peat deposits. Renewable energy developments, including wind farms, and transmission projects are commonly located on upland moorland terrain comprising blanket bog (though raised bogs, intermediate bogs and fens may also be impacted).

Within these settings, peat instability can occur, particularly where thick peat deposits (> 1 m) are present. Peat instability is impacted by numerous factors, including but not limited to:

- Peat thickness;
- Gradient;
- Climate (and rainfall);
- Underlying geology; and
- Subsurface hydrology.

Other anthropogenic factors may also increase the likelihood of peat instability events occurring, which are explored further within this report.

1.2 Objectives

The PLHRA aims to assess the influence of peat on the proposed development and the potential for instability. The objectives have been achieved by completion of the following:

- Geomorphological mapping of the site to identify the prevailing conditions;
- Reporting on evidence of any active, incipient or relict peat instability and the potential risk of future instability, describing the likely causes and contributory factors;
- Identification of potential mitigation and controls to be imposed on the contractors for the works to minimise the risk of peat instability occurring at the site; and
- Peat probing to full depth across the site, within a developable area.

This report summarises the findings of the desk study and two phases of peat surveys and provides an assessment of the prevailing ground conditions at the site and how they relate to peat stability issues.

The results of this assessment were used to inform the iterative design process to avoid areas of increased likelihood of a peat slide and avoid areas of thicker peat.

2. Peat Instability

2.1 Background Information on Peat

Peat is found in extensive areas in the upland and lowland regions of the UK and is defined as the partly decomposed plant remains that have accumulated in-situ, rather than being deposited by sedimentation. When peat forming plants die, they do not decay completely as their remains become waterlogged due to regular rainfall. The effect of waterlogging is to exclude air and hence limit the degree of decomposition. Consequently, instead of decaying to carbon dioxide and water, the partially decomposed material is incorporated into the underlying material and the peat 'grows' in-situ.

Lindsay⁴ defined two main types of peat bog, raised bog and blanket bog, which are prevalent on the west coast of Europe along the Atlantic seaboard. In Britain, the dominant peatland is blanket bog which occurs on the gentle slopes of upland plateaux, ridges and benches and is predominately supplied with water and nutrients via precipitation. Blanket peat is generally considered to be hydrologically disconnected from the underlying mineral layer.

There are two distinct layers within a peat bog, the upper acrotelm layer and the lower catotelm. The acrotelm is the fibrous surface to the peat bog, typically less than 0.5m thick; which exists between the growing bog surface and the lowest position of the water table in dry summers. Below this are various stages of decomposition of the vegetation as it slowly becomes assimilated into the body of the peat.

The degree of humification (decomposition) can be measured in the field via the von Post scale of humification^{5,6}. The 'squeezing test' undertaken in the field provides humification values ranging from H1 (minimal decomposition) to H10 (highly decomposed).

The relative position of the water table within the peat controls the balance between accumulation and decomposition, and therefore its stability, hence artificial adjustment of the water table by drainage can have significant impacts.

2.2 Peat Shear Strength

In geotechnical terms, the shear strength of a soil is the maximum stress that a soil can sustain without experiencing failure. The physical characteristic of a soil impacts on the overall shear strength. For mineral soils such as clay or sands, such strength is variously given by an interparticle friction value and cohesion. Whether the mineral soil is predominately cohesive (clay) or non-cohesive (sand & gravels) governs which of the component strengths control the behaviour of the soil.

In the case of peat soils, where the major constituent is organic, there is likely to be little or no mineral component, the geotechnical definition of shear strength therefore does not strictly apply. At present, there is no real alternative to defining shear strength of peat, therefore the geotechnical definition is usually adopted, in the knowledge that it should be used with caution.

As noted, the acrotelm or near surface peat comprises a tangle of fresh and slightly rotted roots and plant fibres. These roots and fibres impart a significant tensile strength capacity to the material which provides it with a significant load carrying capacity. The acrotelm is in effect, a fibre reinforced soil.

In the more decomposed catotelm, the tensile shear strength is reduced as the roots and fibres become increasingly rotted, however, the loss of strength is offset to a limited degree, by a gain in strength due to

the overburden pressure. In geotechnical engineering there is an established relationship for recently deposited soils, between the shear strength of a sample and thickness of overburden above it.

Consequently, it is almost impossible to predict a shear strength profile in peat and attempts to measure the shear strength using normal geotechnical methods can be misleading (Evans & Warburton 2007⁷; Gosling and Keeton 2008⁸, Winter et al 2005⁹). Typical values of shear strength from hand shear vanes would be in the range 10-60 kilopascal (kPa) although values of over 100 kPa have been recorded in peat elsewhere. The higher strengths are almost certainly influenced by the roots or other non-decomposed material. It is believed that the strength of peat should be quoted as a cohesion value as there are few, if any, discrete particles to give the material a significant frictional resistance. It should be noted that any quotation of shear strength for peat should be treated with extreme caution.

2.3 Peat Failure Characteristics/Mechanisms

This section reviews the nature of peat and how current and past activities can influence stability.

The PLHRA Best Practice Guide for Proposed Electricity Generation Developments, published by the then Scottish Executive (2006, updated by the Scottish Government April 2017¹) determines peat landslide (instability) in two categories, 'peat slides' and 'bog bursts'. It is indicated that peat slides have a greater risk of occurrence in areas where peat depth is shallow (up to 2 m), and slope gradients are steep (5 to 15°). Bog bursts, however, are indicated to have a greater risk of occurrence in areas where peat depth is deep and slope gradients are shallow. As recorded in the Best Practice Guide¹, bog burst events have generally only been reported in Irish and Northern Irish peat bogs. They are uncommon in Scotland and therefore are not considered to attribute significant risk in relation to this assessment. It is noted that peat instability events (including bog bursts), although extremely uncommon, may occur outside the limits mentioned above.

Further to the definition above, a number of natural factors are considered to interact and create the potential for peat instability to occur. These natural factors would typically include:

- Slope Gradient: As noted in the Best Practice Guide¹, peat slides have a greater likelihood of occurrence where slope angles range from 5 to 15°. Deposits with shallower slope gradients are less susceptible to failure due to the reduced influence of gravity. Deposits with steeper slope gradients are less susceptible to failure due to the general lack of peat presence (although peaty debris slide may occur).
- Peat Depth: Boylan et al. (2008)¹⁰ describes three common types of peat, controlled to an extent by rainfall and elevation:
 - Upland Blanket Bog: blanket bogs are typically about 3 m thick, however, they can be up to 5m thick, generally thinning at higher elevations.
 - Lowland Blanket Bog: similar to the upland blanket bog, however, they form around sea level in areas of very high rainfall.
 - Raised Bog: generally 3-12m thick, averaging 7m, with growth occurring above the water table.

Peat depth can give an indication of peat strength and the potential magnitude of a slide, where the generalisation can be made that the potential for peat instability increases with peat depth provided

gradients exist to allow movement. However, when combined with other instability indicators, any depth of peat can fail. Factors that influence the potential include:

- Peat Strength: the shear strength of peat is an important aspect in assessing the risk of landslip in blanket peat areas, with areas of lower shear strength likely to be the cause of any peat slide. However, due to the influence of fibres within the deposits and of stratification with depth, reliable values of shear strength are difficult to near impossible to obtain, using common place in situ and laboratory soil strength tests. Where data is available, it can be used, with extreme caution, to assist in assessing likely risk.
- Relief: the combination of slope gradient and variation in elevation can result in confined and unconfined zones i.e., where undulating or hummocky terrain (confined) exists, the natural relief has the potential to mitigate the occurrence of a peat slide. However, convex sloping hillsides (unconfined) can increase the slide potential.
- Evident and/or Potential Areas of Instability: the presence of certain geomorphological characteristics may signify an increased risk of peat instability. However, peat instability events may occur in areas where no such geomorphological characteristics are present, if the general characteristics match those mentioned above.
- Vegetation Cover: the vegetation cover of an area of bog/mire gives an indication as to its hydrological setting and therefore physical characteristics, as noted in the Best Practice Guide¹ and detailed by Hobbs, 1986⁶.
- Peat Stratification: the peat formation process causes peat to show natural anisotropic strength. The interface between the three distinct layers (indicating three hydroseral stages) within a peat mass is defined by hydrology. The three layers are:
 - Top Mat: living vegetation of herbaceous plants, grasses and mosses;
 - Acrotelm: decomposing peat which is saturated periodically and is of relatively high permeability; and
 - Catotelm: permanently saturated dense peat of relatively low permeability.
 Peat stratification is linked to peat depth (Dykes, 2006¹¹), with thinner peat deposits having a thinner or no catotelm layer. A minimal or absent catotelm layer leads to peat mass having a higher shear strength, as the overlying top mat and acrotelm layers are more fibrous in nature compared to the underlying catotelm layer.
- Hydrology (Surface and Subsurface): surface (seeps and springs, wet flushes, watercourses, concentration of drainage networks etc.) and subsurface (pipe systems, underground channels etc.) drainage pathways can provide areas of peat with a water supply which may be absorbed by and potentially increase the mass of the peat. This can cause pooling/piping within the peat mass, or an increase in water at the base of the peat mass, each of which increases the susceptibility of the peat mass to failure.

The presence of a number of the above natural factors may create the potential for peat instability to occur, however, the actual instability is generally the result of a combination of further contributing factors. These factors have been grouped into two categories within the Best Practice Guide¹ described as preparatory and triggering factors.

Preparatory factors, which affect the stability of peat slopes in the medium to long-term (tens to hundreds of years), are:

- Increase in mass of the peat through peat formation;

¹¹ Dykes, A.P. and Kirk, K.J. (2006) *Slope Instability and Mass Movements in Peat Deposits*. In Martini, I.P., Martinez Cortizas, A. and Chesworth, W. (Eds.) *Peatlands: Evolution and Records of Environmental and Climatic Changes*. Elsevier, Amsterdam.

- increase in mass of the peat through increase in water content;
- increase in mass of the peat through afforestation;
- reduction in shear strength from changes in the physical structure of the peat due to creep, weathering or vertical tension cracks of the material;
- loss of surface vegetation and associated tensile strength (e.g. deforestation);
- changes in the subsurface hydrology (water filled pools and/or pipes etc.); and
- afforestation reducing the water held in the peat body, increasing the potential for formation of desiccation cracks which can be exploited by rainfall on forest harvesting.

Triggering factors, which can have an immediate effect on peat stability and act on susceptible slopes, include:

- intensive rainfall or snow melt causing development of high porewater pressures within the peat;
- alterations to drainage patterns generating high porewater pressures within the peat;
- peat extraction at the toe of the slope i.e. fluvial incision, cut slopes etc. reducing the support of the upslope material;
- peat loading commonly due to stockpiling or plant during construction (or natural causes i.e. landslide) causing an increase in shear stress;
- changes to the vegetation cover i.e. by stripping the surface cover or afforestation; and
- earthquakes or man-made rapid ground accelerations, such as blasting or mechanical vibrations, causing an increase in shear stress.

Evidence of the potential for peat instability within an area may be observed through the recording of the geomorphological conditions of the area. These existing geomorphological characteristics may indicate the presence of existing or historical failures or areas of future potential instability. The characteristics of particular interest include the presence of the following:

- historical failure scars and debris;
- tension cracking and tearing;
- compression ridges/thrusts or extrusion;
- peat creep;
- subsurface drainage (pools and/or piping);
- seeps and springs;
- cracking related to drying;
- concentration of surface drainage networks; and
- the presence of organic clays at the peat and bedrock interface.

2.4 Types of Failures

The result of peat instability is the down-slope mass movement of the peat material. There are several definitions of peat instability which are used to characterise the type of failure, briefly mentioned above but detailed below.

2.4.1 Bog Bursts (or Bog Flows)

Particularly fluid (amorphous) failures involving rupture of the peat blanket surface or margin due to subsurface creep or swelling, with liquefied basal material expelled through surface tears followed by settlement of the overlying peat mass, in-situ (Hemingway and Sledge, 1941-46¹², Bowes, 1960¹³).

Accounts of bog bursts are generally associated with very wet climates or areas which have received storm rainfall events. Bog bursts can be associated with particularly wet peat landscapes; therefore, it is possible to identify broad regions of a higher susceptibility to these failures. The constraints used to identify the areas of higher susceptibility to bog burst failures are given below:

- peat thicknesses >1.5m;
- shallow gradients, ranging from 2 - 10° (peat thicknesses associated with bog bursts are generally not observed on slopes steeper than 10°, where moisture content is reduced due to natural drainage);
- ground which is annually waterlogged to within the upper 1m below ground level (the groundwater level may rise but rarely falls below this level (Crisp et al, 1964¹⁴));
- greater humification of the lower catotelm within the waterlogged ground; and
- lower surface tensile strength of the fibrous peat and vegetation.

The humified mass can be considered as analogous to a heavy liquid and the stability of this mass is maintained by the strength of the surface or acrotelm peat. Should the surface become weakened through erosion or desiccation or the construction of a surface drainage ditch for agricultural or forestry reasons or through turbary (peat cutting), failure is made more likely.

2.4.2 Peat Slides

Peat slides tend to be translational failures with a defined shear surface at or close to the interface with the substrate. The factors generally considered to influence susceptibility to peat slide failures are listed below:

- Peat depth up to 2m;
- Slope gradients between 5 and 15°;
- Natural or artificial drainage cut into the surrounding peat landscape;
- Greater humification of the lower catotelm within the waterlogged ground; and
- Lower surface tensile strength of the fibrous peat and vegetation.

It is noted that some of the factors causing instability are common to both bog bursts and peat slides. The peat – substrate interface is the primary zone of failure and is enhanced by elevated water content at this boundary and softening or weathering of the lower mineral surface. For this reason, any investigation or probing should try to distinguish the nature of the lower mineral substrate.

2.4.3 Bog Slides

A bog slide is a variation on a peat slide where part of the peat mass is subject to movement, usually on an internal layer of material, which may be more prone to movement, such as an interface between the acrotelmic and catotelmic layer.

¹² Hemingway, J.E. and Sledge, W.A. (1941-46) *A Bog Burst near Danby in Cleveland*.

Proceedings of the Leeds Philosophical and Literature Society, Science 4, pp276 – 288.

¹³ Bowes, D.R. (1960) *A bog burst in the Isle of Lewis*. Scottish Geographical Magazine, 76, pp21-23

¹⁴ Crisp, D.T., Dawes, M. & Welch, D. (1964), 'A Pennine Peat Slide', The Geographical Journal, Vol 130, No4, pp519-524.

2.5 Natural Instability

The stability of a peat mass is controlled by a complex interrelationship of factors. Key factors include sloping rock head, and proximity to water bodies. Rainfall often acts as a trigger after the slope has been conditioned to fail by natural processes.

It should also be remembered that peat bogs are growing environments and that there would come a time, on sloping ground, where the forces causing instability, the weight of the bog, can no longer be resisted by the internal strength of the peat and its interface with the underlying mineral surface. At this point, failure would occur.

The weight of the peat bog or any soils mantling steep hill slopes would be increased during periods of very heavy rain and it is common to see landslips occurring following extreme rain events. This may be a concern for future developments where one of the predicted effects of global warming is greater frequency of extreme weather, including intense storm events.

3. Desk Based Assessment

A desk-based review of the site and its condition has been conducted using the following sources of information:

- British Geological Survey (BGS) mapping and data;
- Scottish Natural Heritage (SNH) (now NatureScot) Carbon and Peatland Map, 2016;
- Hydrogeological Map of Scotland, BGS, 1988;
- Soil Survey of Scotland Maps, James Hutton Institute;
- Aerial photography;
- Ordnance Survey and topographic maps; and
- Historical mapping.

3.1 Baseline Conditions

3.1.1 Geological Setting

3.1.1.1 Superficial Geology

Published geological mapping from the BGS at 1:50,000 scale indicates that superficial deposits are absent across much of the site extent. Indicating that bedrock is anticipated to be at or near to the surface. Alluvial (clay, silt, sand, gravel) deposits flank the watercourses present across the site with Glacial Till mapped upslope of the main watercourse channels but absent on hill tops. BGS mapping indicates that there is only a small amount of peat expected at the site, which can be found in the north and north-east of the site in localised areas close to North Hart Law, as shown in Figure 3.

3.1.1.2 Soils

The NatureScot (formerly SNH) Carbon and Peatland Map¹⁵ characterises the site as not having any areas designated as priority peatland. To the north of the site there is a large area of Class 5 peatland. Class 5 peatland is considered that soil information takes precedence over vegetation data, there are no peatland habitats recorded, but may also include areas of bare soil and soils that are carbon-rich and deep peat.

The National Soil Map of Scotland indicates the site primarily comprises brown soils across the south extent of the site, Alluvial soils across the central area of the site and Peat in the north extent of the site.

An initial phase of peat depth surveying was undertaken to gather site specific information on the presence and condition of peat soils and/or peat and is described further in Section 4.

3.1.1.3 Bedrock Geology

BGS 1:50k mapping indicates that the bedrock geology underlying the site predominately comprises Silurian age sedimentary bedrock of the Gala Group (wacke sandstone, with siltstone and mudstone in variable proportions). There are numerous intrusive igneous rocks present across the site, ranging in age from Siluro-Devonian (predominately comprising felsic and granitic rocks) to Carboniferous (mafic rocks).

The bedrock geology at the site and adjacent area, are detailed within Table 3-1 and Figure 4.

¹⁵ Scottish Natural Heritage (SNH) (2016). *Carbon and Peatland Map*. Available at <https://soils.environment.gov.scot/maps/thematic-maps/carbon-and-peatland-2016-map/>

Table 3-1
Summary of Bedrock Geology

Stratigraphy				Description
Age	Group	Formation	Member	
Palaeogene	-	-	Mull Dyke Swarm	Olivine-basalt
Carboniferous	North Britain Late Carboniferous Tholeiitic Suite	-	Central Scotland Late Carboniferous Tholeiitic Dyke Swarm	Quartz-microgabbro
			Dinantian Dykes	Monchiquite, Basalt and Microgabbro
		-	Unnamed Igneous Intrusion	Microgranitic, rock
Siluro - Devonian	-	-	North Britain Siluro Devonian Calc-Alkaline Dyke Suite	Microgranite, Porphyritic. Microdioritic-rock. Microdioritic, Porphyritic
	Reston Group	Great Conglomerate Formation	-	Red and purple conglomerates, fine- to coarse-grained, chiefly composed of rounded greywacke pebbles and boulders in a red-brown sandstone matrix with some interbedded pebbly sandstones, thin red-brown siltstones and mudstones.
Silurian	Gala group	Mindork Formation	-	Graded beds that may include wacke sandstone, siltstone and mudstone in variable proportion, interpreted as turbidites.
		-	-	Graded beds that may include wacke sandstone, siltstone and mudstone in variable proportions, interpreted as turbidites.
Ordovician - Silurian	Moffat Shale Group	-	-	Black shale, grey shale, bentonite, tuff.
Ordovician	Leadhills Supergroup	-	-	Greywackes, shales, siltstones and mudstones with conglomerates.

3.1.1.4 Mining and Quarrying

The site is not located within a historical mining area, a review of BGS and aerial photography mapping shows no active or ceased mines or quarries within the site boundary. There are some localised borrow pits alongside the existing track network but there is no reason to expect any larger-scale excavation have taken place on the site.

3.1.2 Hydrology and Climate

3.1.2.1 Hydrology

The site lies within the surface water catchment of the River Tweed within the Solway Tweed River Basin District. The Whalplaw Burn (ID 5277) and the Soonhope Burn (ID 5276) transverse the site flowing from north to south, meeting at E350790, N654361 to become the Cleekhimin Burn, flowing into the Leader Water. Leader Water joins the River Tweed approx. 20km south of the site, east of the town of Melrose. Whalplaw Burn and Soonhope Burn are classified by SEPA as having an overall condition of 'Good' under the Water Framework Directive (WFD).

3.1.2.2 Hydrogeology

The primary groundwater unit underlying the site is the Gala Group which is a low productivity aquifer. The unit is described as “highly indurated greywackes with limited groundwater in near surface weathered zone and secondary fractures”. Its primary source of flow is through these secondary fractures and other discontinuities.

The groundwater unit is located within the Lauder, and Peebles, Galashiels and Hawick groundwater body which have an overall condition classification of ‘Good’ under the Scotland River Basin Management Plan (RBMP) as required by the Water Framework Directive.

3.1.2.3 Rainfall

The nearest Met Office weather station to the proposed development site is approximately 20km southwest at Galashiels (E348901, N636980). The average annual rainfall for the period 1991-2020 was 832.58 mm, which is 30% less than the Scotland East regional average, and 50% less than the Scotland-wide average. On average the wettest months are in August, October, and December. Periods of intense heavy rainfall can increase the likelihood of peat slides occurring.

3.1.3 Land Use and Topography

The site primarily comprises heather moorland or rough grassland. On Longcroft Hill there are areas of coniferous plantation, as well as rectilinear fields boundaries.

The site is characterised by a central valley with steep gradients increasing in elevation from the valley to the east and west of the site. Steep gradients are present in the east of the site where the hill plateaus. The north of the site reaches a more consistent elevation at South Hart Law. The site has been characterised into slope classes based on 5m Digital Terrain Model (DTM) and is shown in Figure 6.

3.1.4 Aerial Photography and Site History

3.1.4.1 Aerial Photography Interpretation

The aerial photography was interpreted, and it was possible to identify changes in vegetation and drainage patterns. The aerial photographs were used in conjunction with the site DTM data to identify the major geomorphological features, mainly as breaks of slope, significant watercourses etc. The site was further assessed during site visits when more detailed mapping was undertaken.

Interpretation of available aerial photographs was undertaken to assess and identify (where present) evidence of historic peat instability. The photographs were examined to highlight features of interest, where present, including:

- Possible extension and/or compression features;
- Areas of historic failure scars and debris;
- Evidence of soil or peat creep;
- Areas with apparent poor drainage;
- Areas with concentrations of surface drainage networks;
- Steeply incised stream cuttings within peat deposits; and
- Active and historic peat cuttings.

The aerial photography, DTM and data gathered on site have been used in conjunction to create a geomorphological interpretation of the site, presented in Figure 8.

The predominant features identified from the aerial photography are steeply incised slopes associated with watercourses, changes in vegetation, electrical infrastructure (overhead line), the existing track network as well as historic borrow pit extraction.

There was no evidence visible in the historic photographs of any extension or compression features in the peat. It was not possible to identify evidence of any significant historic peat failures or slides within the limited peat areas, from the aerial photographs

3.1.4.2 Historic Mapping

Freely available historic OS mapping has been reviewed, there was no evidence of historic instability identified within the limited peat areas.

3.1.4.3 Local Knowledge

No anecdotal background from landowners or past site users has been provided to suggest there has been a history of peat instability on the site.

3.2 Surface Water and Sensitive Receptors

The effects of peat failures are felt locally, both in the long and short term, but they can also have wider off-site implications.

A key part of the risk assessment process is to identify the potential scale of peat failure, should it occur, and identify the potential environmental effects as well as the receptors of such an event.

Peat failure associated with the proposed development could affect the following key receptors:

- The proposed development itself including associated infrastructure;
- Property and infrastructure, for example roads or utilities;
- Land based ecological effects (damage to habitats);
- On-site and downstream watercourses;
- Archaeological assets; and
- Visual amenity (scarring of the landscape).

4. Site Work

4.1 Peat Depth Survey

Phase 1 Peat probing was undertaken across the site within a developable area, in early March 2023 by ITPEnergised, with phase 2 probing undertaken in July – August 2023. Phase 2 probing targeted areas adjacent to where phase 1 probing identified soils > 0.5m and/or where ecology surveys indicated potential peatland habitat.

4.1.1 Methodology

The surveys carried out followed best practice guidance for development on peatland.

The thickness of the peat/soils was assessed using a graduated fibre glass peat probe (with a maximum depth of 10m). This was pushed vertically into the peat/soil to refusal and the depth recorded using a handheld Trimble Global Positioning System instrument (GPS), reaching an accuracy of <1m.

Alongside desk-based information, the ‘feel’ on refusal was used to interpret the underlying substrate. The following criteria was used in the field:

- Solid and abrupt refusal – Rock
- Solid but less abrupt refusal with grinding or crunching sound – Granular (sands, gravel, weathered rock)
- Gentle refusal – Cohesive (Clay/Silt)

4.1.2 Peat Depth Analysis

A summary of the peat depths encountered during probing is detailed in Table 4-1 below and within Figure 5.

Table 4-1 Distribution of Peat Depth Recorded at the Site

Peat Depth Interval (m)	Number of Occurrences (Ph1)	% of Probes (Ph1)	Number of Occurrences (Ph2)	% of Probes (Ph2)
0	6	0.7	13	2.0
0.01 – 0.5	798	94.1	621	95.2
0.51 – 1.0	32	3.8	16	2.5
1.01 – 1.5	7	0.8	1	0.2
1.51 – 2.0	2	0.2	1	0.2
2.01 – 2.5	2	0.2	0	0
2.51 – 2.8	1	0.1	0	0
> 2.8	0	0.0	0	0
Total	848	100	652	100

The results of the probing show that 94.6% of probes recorded across both phases ranged between 0 to 0.50m in depth, i.e. mineral and peaty soils, not peat. Overall there is very little peat present across the site, with limited localised deposits in the north and east of the site. During targeted probing of infrastructure locations (phase 2), greater than 95% of probes identified soils < 0.5m in depth. The distribution of peat generally aligns with superficial geology mapping, with the proposed development avoiding areas of peat, as shown in Figure 5.

4.1.3 Substrate

The underlying substrate was generally recorded as granular soils. There were some instances of cohesive soils (silt/clay) recorded however the majority was granular. Where fresh rock was exposed or found near surface, there was generally no peat recorded.

5. Peat Landslide Hazard and Risk Assessment

The Best Practice Guide¹ acknowledges that there is no universal agreed definition of hazard and risk that can be applied in the context of peat landslides.

The guidance describes the calculation of risk from the following formula:

$$\text{Risk} = \text{Likelihood of a Peat Landslide} \times \text{Adverse Consequence}$$

The guidance provides examples of assessment methodology to be used. ITPEnergised have reviewed the guidance and the approach of other leading experts and has undertaken the assessment using the following methodology.

Firstly, it is important to note that the proposed development, including siting of wind turbines (noting that the initial layout comprised 24 turbines) and other infrastructure, resulted from an iterative process which took into account the findings from peat survey work. Deeper peat was avoided wherever possible, in order to minimise the requirement to disturb and/or excavate peat, and to minimise peat slide risk associated with construction across and within peat. The final layout comprises 19 wind turbines.

The first phase of assessment is to identify the susceptibility or likelihood of a peat landslide occurring based on existing conditions and parameters that influence peat landslide occurrence (prior to influence of construction).

Once areas of increased likelihood of a peat slide occurring have been identified, an assessment of adverse consequence (impact) and risk assessment would be undertaken on these areas, assessing the impact of a potential peat slide on identified receptors. For this further assessment, impact coefficient scores are determined, combined with an assessment of the vulnerability of receptors to establish a final risk score.

5.1 Likelihood Assessment

The susceptibility or likelihood of a peat slide occurring is controlled by a number of natural controlling and trigger factors. These are typically:

- Slope gradient;
- Peat depth;
- Peat strength;
- Nature of the substrate beneath peat deposits;
- Relief;
- Evidence of historical failures/potential instability (e.g. tension cracks, creep, compression ridges);
- Vegetation cover;
- Land use; and
- Hydrology.

The most important of the above controlling factors are considered by the assessor to be peat depth, slope gradient, underlying substrate and evidence of potential instability (which is controlled by the former). Without peat and slope, the risk of a peat slide would be unlikely to exist.

These key parameters influencing peat stability have been scored and provided a coefficient value.

The Best Practice Guide¹ relates the likelihood of a peat landslide to a scale of 1 to 5, with 1 being negligible (very low likelihood) and 5 being almost certain (very high likelihood). This scale relates to the likelihood of instability for all the controlling factors under consideration.

It is important to note that this study only focuses on peat soils and the criteria used is specifically tailored to the key factors affecting peat stability. As such it does not account for the stability of other mineral soils or rock.

Peat strength has not been included as a factor in the likelihood scoring process. Site specific peat strength data was not collated for the site given the difficulty in obtaining reliable values of shear strength using common place in situ and laboratory soil strength tests (as described in Section 2.2). The shear strength is also linked to peat depth as strength is considered to decrease with thickness. As such this parameter is considered to be factored into the risk scoring for peat depth.

5.1.1 Input Data

The input data sets used for the analysis were as follows:

- Slope gradient: Terrain 5 DTM with a 5m grid size;
- Peat depth: Site survey information for peat depth and site observations;
- Nature of substrate: Surveyor observations of substrate “feel” at the refusal point during probing, together with BGS geological mapping and surveyor observations of exposed substrate at the site;
- Emerging Instability: Where there is evidence of instability or factors which may increase the likelihood of a slide event occurring e.g. soil creep, slumping, possible extension/compression features, poor drainage etc.

The assessment firstly considers the likelihood of instability occurring, based on a series of input factors. These factors were attributed coefficient scores based on their influence on peat stability.

There is no guidance available on how to combine the likelihood scoring for each of the factors used in the assessment. The assessment team have used the methodology set out below.

For each of the factors noted, a score/coefficient of zero to three has been assigned. A zero score reflects no contribution to peat slide likelihood, with a score of three indicating a high peat slide likelihood associated with that factor.

The total likelihood ranking is the product of the four individual factor scores.

5.1.1.1 Slope Angle

The limiting factor governing the formation of thick peat deposits is topography. In the case of blanket peat, it tends to be deepest in closed depressions, and typically thin as the slope angle increases (Boylan et al. 2008¹⁰). The Best Practice Guide¹ details that a PLHRA is not needed for blanket bog sites with slopes less than 2° and as such, a score of zero has been assigned for slopes less than 2°. For slopes greater than 2°, scores have been assigned based on the type and nature of peat slides reported for different slope conditions.

A slope angle GIS layer was generated from the DTM at a 5m cell resolution. The source DTM is also at a 5m resolution. The slope angle details are illustrated in Figure 6.

This slope, calculated in degrees, was identified at each probe location and scored as shown in Table 5-1.

Table 5-1 – Coefficient for Slope

Slope (degrees)	Slope Coefficient	Notes
2.0 or less	0	Failure unlikely due to flat ground
2.1 – 5.0	2	Failure in blanket bog areas would typically occur as peat slides and peaty debris slides, due to low slope angle.

Slope (degrees)	Slope Coefficient	Notes
5.1 – 15.0	3	Failure in blanket bog areas would typically occur as peat slides, bog slides or peaty-debris slides. This is the key slope range for reported peat failures.
15.1 – 20.0	2	Failure would typically occur as peaty debris slides due to low thickness of peat on steeper slopes.
>20.0	1	Failure would typically occur as peaty debris slides due to low thickness of peat on steeper slopes.

5.1.1.2 Peat Depth

Peat thickness is seen as one of the key factors associated with peat stability. Typically, the deeper the peat the more humified, and therefore potentially weaker and unstable it is. Peat depth surveys have been completed on the site and these data were then interpolated using the Spline interpolation function within the Spatial Analyst Tools of ArcMap 10.3 (see Figure 5).

The highest hazard scores have been assigned to peat depth ranges most frequently associated with peat slides on upland sites (Evans and Warburton, 2007⁷).

The peat depth was identified at each probe location and scored as shown in Table 5-2.

Table 5-2 – Coefficient for Peat Depth

Peat Depth (m)	Depth Coefficient	Notes
Nil	0	No peat/organic soil therefore no potential for peat slide
<0.5	1	Peaty/organic soil rather than peat, therefore failures would be peaty-debris slides
0.5 – 1.5	3	Sufficient peat thickness for peaty debris or peat slide
>1.5	2	Sufficient peat thickness for peat slide however less often recorded at this thickness, due to thicker peat generally occurring in areas of shallow gradients

5.1.1.3 Substrate

The nature of the substrate beneath peat deposits can have a bearing on the likelihood of instability arising, with failure often occurring at the interface between the base of the peat mass and the top of the substrate.

Where granular soils (sand/gravel derived from glacial till) or weathered rock form the substrate, the effective strength of the interface can be considered to be good, with comparatively high friction values. Under these conditions, failure is likely to occur in a zone within the peat, just above the interface. Further

factors are necessary to cause a failure of this nature (increased pore pressures within the peat) and occurrence of such events is rare.

Where cohesive soils (clay) form the interface, there is likely to be a significant zone of softening in the clay (due to saturation at low normal stresses, poor or non-existent vertical drainage and the effect of organic acids), resulting in either very low undrained shear strength or low effective shear stress parameters. The result is that potential shearing could occur either in the peat, or in the interface or in the clay; all three possibilities have been documented in peat slides.

A rock substrate provides a high strength stratum; however, the rock surface can be smooth, with a relatively impermeable surface which can result in a 'slippery' interface. This can allow accumulation of groundwater and/or low shear strength at the interface, resulting in a higher susceptibility for the overlying peat mass to fail.

The nature of the substrate was inferred at each probe location, based on surveyor observations and BGS geological mapping, and scored as shown in Table 5-3.

Table 5-3 – Coefficient for Substrate

Substrate	Substrate Coefficient	Notes
Granular – Sands/Gravels/Weathered rock	1	Peat failures sometimes associated with bedrock or granular till substrate
Cohesive (clay)	2	Peat failures often associated with cohesive till substrate
Rock (smooth interface)	2	Peat failures often associated with impermeable 'smooth' bedrock surface.
Not proven	3	If the overall thickness of the peat had not been proven, the risk associated with the significant thickness and the unknown substrate would be given a high rating to accommodate unknown factors.

5.1.1.4 Evidence of Existing or Emerging Instability

Geomorphological considerations such as peat erosion, hagging, peat pipes, pools, and evidence of existing instability, can contribute to the potential for instability to arise.

Where evidence of existing or emerging instability was identified by surveyor observations or through mapping and aerial photography a coefficient score has been assigned, as shown in Table 5-4.

**Table 5-4 – Coefficient for Existing or Emerging Instability**

Evidence of Existing/Emerging Instability	Existing or Emerging Instability Coefficient	Notes
Yes	2	Failures likely to occur where evidence of emerging/developing instability is observed (peat pipes/collapsed pipes, areas of diffuse surface drainage such as flushes and pools, tension cracks, compression ridges, bulging, quaking bog) or in areas in close proximity to previous failure events.
No	1	No impact on likelihood of peat slide

5.1.2 Likelihood Rating

The coefficient scores assigned for each of the above factors were multiplied to give a likelihood rating.

Identification of the likelihood of a peat landslide occurring is the first step of the assessment, allowing areas of potential concern to be identified.

Table 5-5 sets out the ranking system employed in this assessment.

Table 5-5 – Likelihood of a Peat Landslide Occurring

Likelihood Rating Coefficient	Likelihood of Instability	Action
0	None	No mitigation required; good construction practices should be followed.
1 - 5	Negligible	No mitigation required; good construction practices should be followed.
>5 - 15	Low	Further investigation to refine assessment and mitigate hazard through relocation or re-design at these locations.
>15 - 30	Medium	Should not proceed unless risk can be avoided or mitigated at these locations, without significant environmental impact, in order to reduce likelihood score to low or negligible.
>30 - 36	High	Avoid project development at these locations
>36 - 54	Very High	Area should be avoided due to very high level of risk and almost certain likelihood of a peat slide occurring.

The assessment of all probe locations is included in Annex 2. The results show that of the 1500 probe locations within the extent of the DTM, the following likelihood ratings were identified:

- No or Negligible likelihood at 1400 locations;
- Low likelihood at 93 locations and
- Medium likelihood at 7 locations.

No high or very high likelihood locations were identified. Figure 7 provides the interpreted likelihood of peat stability based on the rating calculated from the above factors. A summary of the likelihood of peat instability at proposed turbine locations is shown in Table 5-6 below.

Table 5-6 – Likelihood of Peat Instability Rating at Turbine Locations

Infrastructure Element	Likelihood of Instability Rating	Average Peat Depth (m)	Slope (degrees)	Suitability of Location
T1	Negligible	0.1	5.23	Suitable
T2	Negligible	0.1	6.51	Suitable
T3	Negligible	0.17	2.72	Suitable
T4	Negligible	0.1	6.39	Suitable
T5	Negligible	0.1	3.61	Suitable
T6	Negligible	0.1	3.80	Suitable
T7	Negligible	0.2	4.38	Suitable
T8	Negligible	0.2	6.39	Suitable
T9	Negligible	0.2	1.07	Suitable
T10	Negligible	0.2	3.85	Suitable
T11	Negligible	0.2	5.64	Suitable
T12	Negligible	0.3	4.93	Suitable
T13	Negligible	0.2	5.49	Suitable
T14	Negligible	0.2	6.91	Suitable
T15	Negligible	0.1	5.08	Suitable
T16	Negligible	0.2	4.99	Suitable
T17	Negligible	0.2	6.34	Suitable
T18	Negligible	0.1	3.69	Suitable
T19	Negligible	0.1	5.86	Suitable

As can be seen from Table 5-6, no turbine locations are situated on peat (>0.5 m) and the likelihood of a peat slide occurring has been deemed negligible at all locations. These rankings accord with very limited peat deposits being present on the site and turbines generally being located on low to moderate slopes.

No proposed infrastructure is situated on a ranking greater than low, with the majority deemed negligible.

5.2 Results

The likelihood assessment has determined that the majority of the site lies within an area of negligible or low likelihood of a peat landslide occurring (Figure 7). Where medium risks have been identified, these are

associated with thin peat deposits sited on moderate to steep slopes. These locations are not within influencing distance of proposed infrastructure and therefore a detailed impact assessment is not considered necessary.

6. Design and Mitigation

6.1 Detailed Design and Site Investigation

A detailed site investigation would be required to assist detailed design, comprising intrusive ground investigations at infrastructure locations prior to construction commencing, to ascertain depth to bedrock and suitable founding conditions.

If unexpected peat deposits were identified, a detailed stability analysis can then be completed at all infrastructure locations using the increased confidence in the shear strength/peat depth data and site-specific topographical survey data, to provide added robustness to the stability assessment.

6.1.1.1 Mitigation

The infrastructure would not be constructed on peat, rather peat would be excavated to allow founding onto a suitable stratum i.e. bedrock.

It is anticipated that extraction of rock will be required in at least some areas to create suitable levels for founding turbines and hardstandings.

Prior to construction, a specific construction method statement would be produced which would draw on the findings of intrusive investigations. The method statement would detail the exact construction methodology to be used and taking into account:

- Opportunities for micro-siting turbines and hardstandings to further minimise risk where possible;
- A geotechnical analysis for each turbine base;
- The method of excavation and the location for placing and storing excavated material to ensure that these operations do not give rise to slope or site instability;
- Methodology for storing and watering surface vegetated turves, for re-sodding bare areas;
- Details of how excavated spoil would be stored;
- Avoidance of construction (if possible) on wet areas, flushes and easily eroded soils;
- Adequate drainage design to cater for expected heavy rainfall events; and
- Monitoring of ground movement and water levels.

The Construction Method Statement would also detail how pumped water from excavated bases would be controlled and monitored to ensure it is appropriately managed and if directed into or conveyed to existing drains/watercourses, to ensure that all have adequate treatment beforehand and capacity to deal with the volumes of water encountered.

6.1.2 Monitoring and Management

A line of surveyed and levelled pegs and visual monitoring is an acceptable method of monitoring movement adjacent to roads, excavations and stockpile areas.

Thus, as construction activities commence, the appearance of the area and surrounding land would be monitored visually by installing a line of levelled pegs adjacent to the activity location. Specifically, the following signs would be looked for:

- An increased rate of sinking or tilting;
- The rising of adjacent peat/peaty soils;

- Cracking and lateral movement of the soil surface; and
- A rise in water levels.

The Principal Contractor would ensure that suitably qualified and experienced construction staff are engaged on the project, including a senior geotechnical engineer with extensive practical knowledge and experience of similar conditions to those at the site. The senior geotechnical engineer would have responsibility for maintaining and actively monitoring a geotechnical risk register for the construction works.

Additionally, all staff would undergo a site induction and suitable training relating to construction on peatland sites. This would raise awareness of ground instability indicators, best practice construction techniques, mitigation and emergency procedures. All staff should be responsible for observational monitoring and reporting.

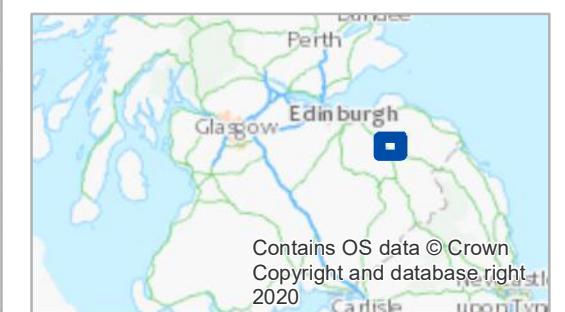

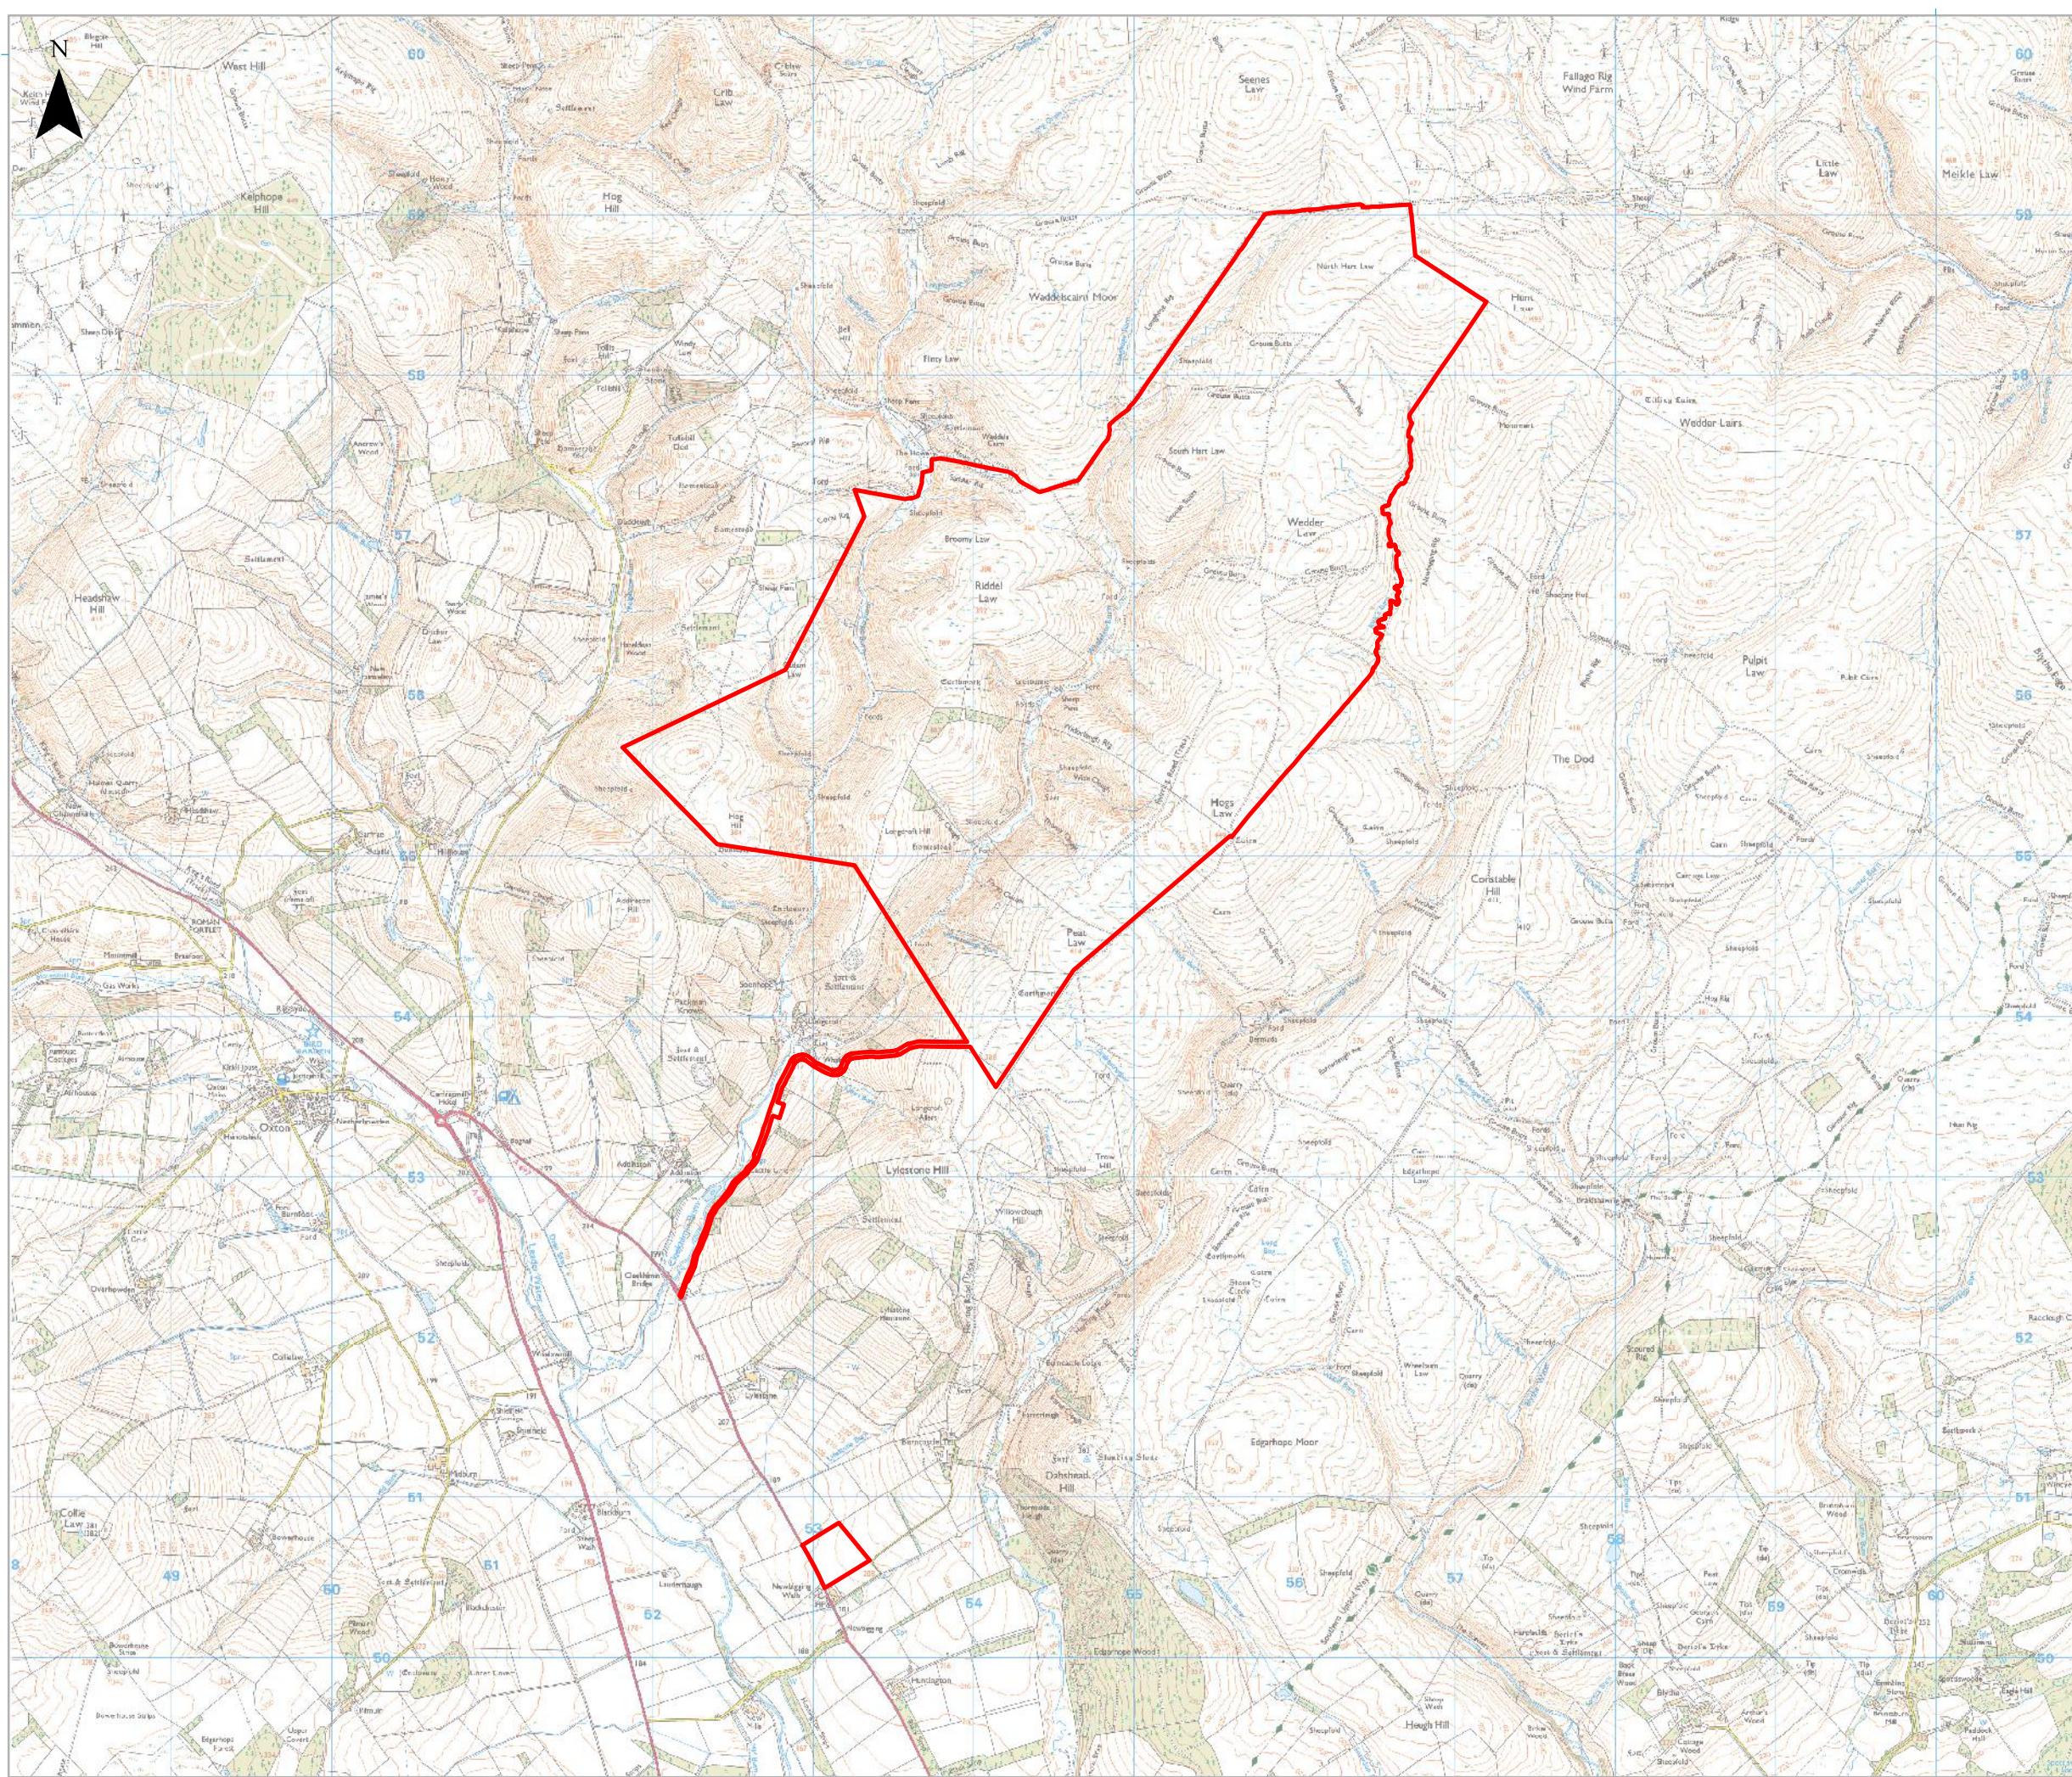

7. Conclusion

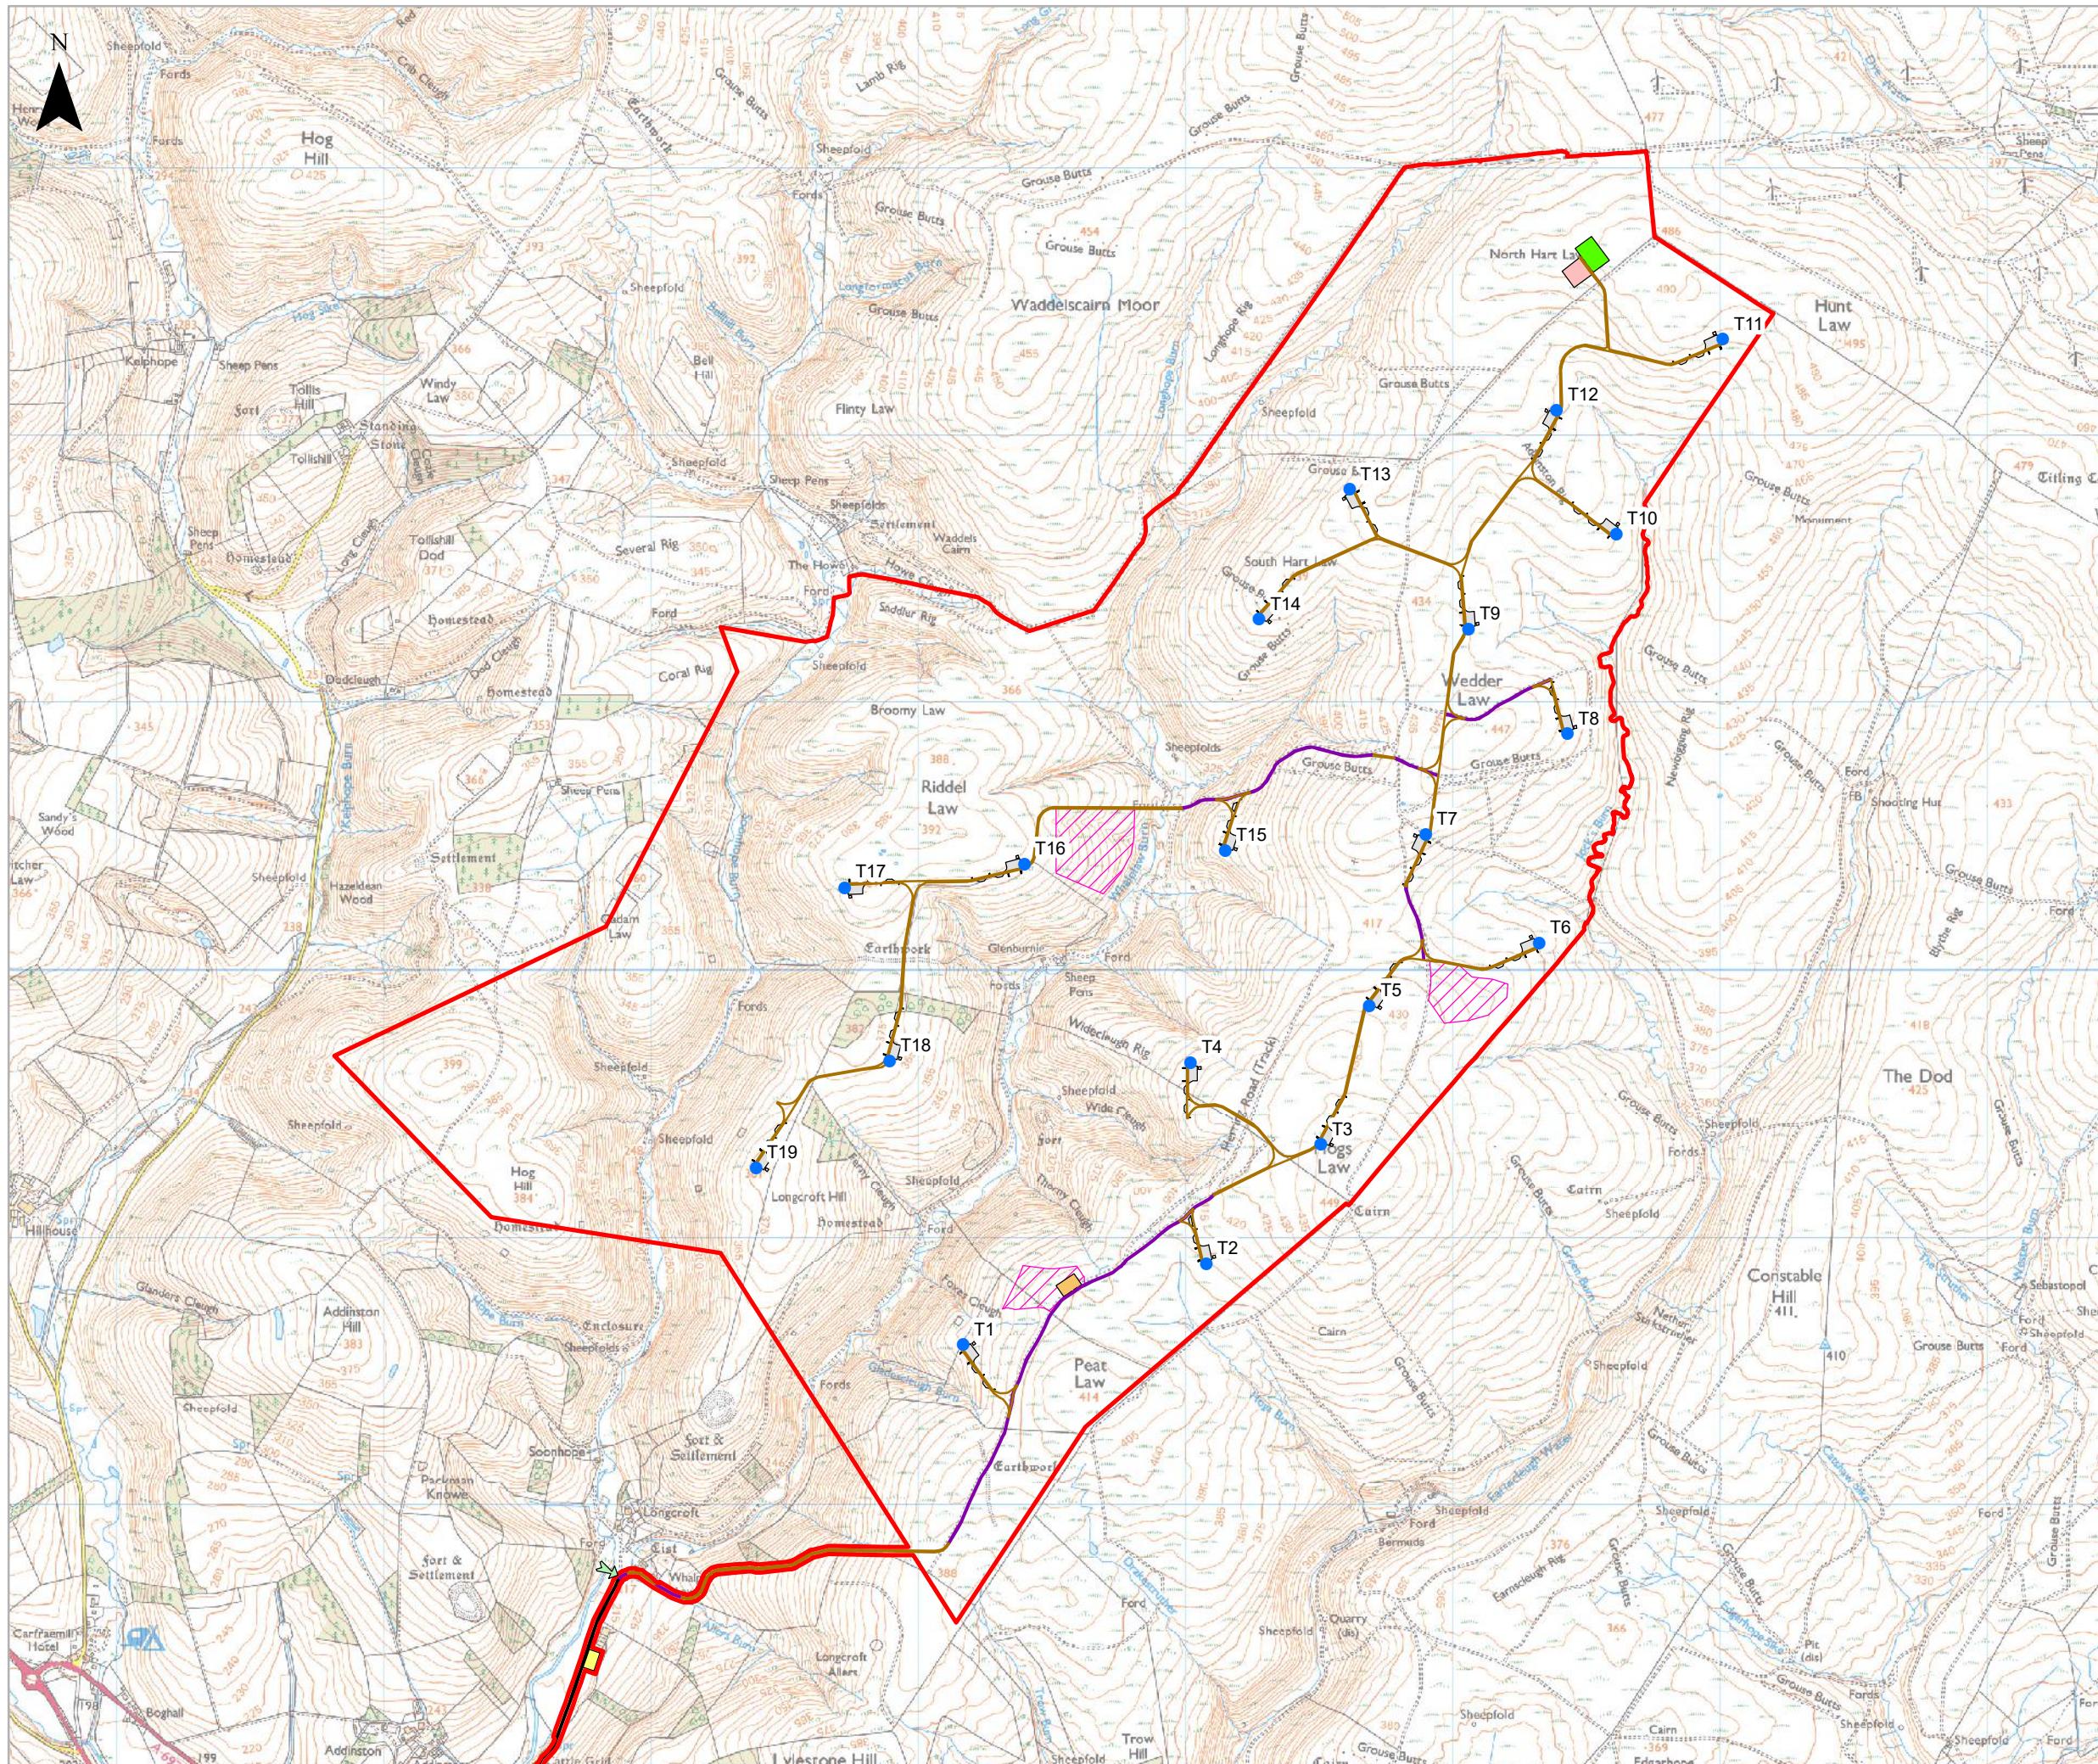

The proposed development has been assessed for potential peat instability through consideration of the likelihood of a peat slide occurring based on existing site conditions. Two phases of peat depth surveys have shown that there is very little peat present across the site, with limited localised deposits in the north and east of the site. The proposed development infrastructure, which was developed through an iterative design process generally avoids peat.

Although the identified likelihood is recorded to be negligible to low across the majority of the site, good construction practices and appropriate mitigation should be followed, with construction works supervised by a suitably qualified geotechnical specialist.
